

Formica fusca f. *fusco-lemani* m. n.

It connects the signs of both *F. fusca* L. f. typ. and *F. fusca* r. *lemani* Bondr. They are the colonies in which the specimens occur partly with the erect hairs on the dorsum of thorax, partly quite bare. The colour of extremities fluctuates from yellow to the brown. The bronze tinte is missing mostly. There are many authors speaking about the form of these characters.

Lok.: Boh.: Húrka hill near Mladějov in B. (lgt. et coll. Samšiňák); Peřimov (lgt. Dlabola, coll. Záleský). Mor.: Kroměříž (lgt. Fiala, coll. Záleský).

Formica fusca r. *lemani* f. *šulci* m. n.

It is distinguished by dense whitish pubescence over all the surface of the body from which it receives a strong silk lustre, so that it is quite similar to the *F. fusca* r. *glebaria* Nyl. It has however the erected hairs on the dorsum of thorax and bright legs.

Called to the honour of J. ŠULC who has deserved about the coleopterological investigation of the surroundings from Sobotka.

Lok.: Podsemín near Sobotka, N. E. Bohemia.
