

development of the larva may be drastically modified. In the junior author's colony eight males emerged during the period from July 3 to July 24, 1963. These males developed from eggs which had been laid in June of 1962. These eggs developed into larvae in about a month and the larvae grew for about two months. But from September 1962 to June 1963 the larvae showed no further development. In short, these eight males over-wintered as larvae. They emerged in July and it is interesting to note that the marriage flight of *rohweri* occurs in that month. The senior author took a female of *rohweri* which had just completed her marriage flight in Baboquivari Canyon on July 28, 1951.
